

dsPIC33E/PIC24E

dsPIC33E/PIC24E Flash Programming Specification

1.0 DEVICE OVERVIEW

This document defines the programming specification for the dsPlC33E 16-bit Digital Signal Controller (DSC) and PlC24E 16-bit Microcontroller (MCU) families. This programming specification is required only for those developing programming support for the dsPlC33E/PlC24E family. All other customers should use development tools that already provide support for device programming.

Topics covered include:

- Section 1.0 "Device Overview"
- Section 2.0 "Programming Overview of the dspic33e/PIC24E"
- Section 3.0 "Device Programming Enhanced ICSP"
- Section 4.0 "Checksum Computation"
- Section 5.0 "The Programming Executive"
- Section 6.0 "Device Programming ICSP"
- Section 7.0 "Programming the Programming Executive to Memory"
- Section 8.0 "Device ID"
- Section 9.0 "AC/DC Characteristics and Timing Requirements"
- Appendix A: "Hex File Format"
- Appendix B: "Revision History"

2.0 PROGRAMMING OVERVIEW OF THE dsPIC33E/PIC24E

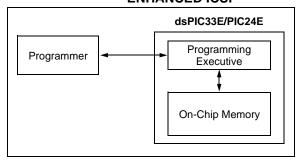

There are two methods of programming the dsPIC33E/PIC24E family of devices discussed in this programming specification. They are:

- In-Circuit Serial Programming[™] (ICSP[™]) programming capability
- · Enhanced In-Circuit Serial Programming

The ICSP programming method is the most direct method to program the device; however, it is also the slower of the two methods. It provides native, low-level programming capability to erase, program and verify the chip.

The Enhanced ICSP protocol uses a faster method that takes advantage of the programming executive, as illustrated in Figure 2-1. The programming executive provides all the necessary functionality to erase, program and verify the chip through a small command set. The command set allows the programmer to program the dsPIC33E/PIC24E Programming Specification devices without having to deal with the low-level programming protocols of the chip.

FIGURE 2-1: PROGRAMMING SYSTEM OVERVIEW FOR ENHANCED ICSP™

This specification is divided into major sections that describe the programming methods independently. Section 3.0 "Device Programming – Enhanced ICSP" describes the Enhanced ICSP method. Section 6.0 "Device Programming – ICSP" describes the ICSP method.

2.1 Required Connections

These devices require specific connections for programming to take place. These connections include power, VCAP, MCLR, and one programming pair (PGEDx/PGECx). Table 2-1 describes these connections (refer to the specific device data sheet for pin descriptions and power connection requirements).

Note: Refer to the specific device data sheet for complete pin diagrams of dsPIC33E/ PIC24E devices.

TABLE 2-1: PINS USED DURING PROGRAMMING

During Programming						
Pin Name	Pin Type	Pin Description				
MCLR	I	Programming Enable				
VDD, VUSB, and PAVDD		Power Supply ⁽¹⁾				
Vss and AVss	Р	Ground ⁽¹⁾				
VCAP	Р	CPU Logic Filter Capacitor Connection				
PGECx	I	Programming Pin Pair: Serial Clock				
PGEDx	I/O	Programming Pin Pair: Serial Data				

Legend: I = Input O = Output P = Power

Note 1: All power supply and ground pins must be connected including AVDD, VUSB, and AVSS.

2.2 Program Memory Write/Erase Requirements

The program Flash memory on the dsPIC33E/PIC24E has a specific write/erase requirement that must be adhered to for proper device operation. The rule is that any given word in memory must not be written without first erasing the page in which it is located. Thus, the easiest way to conform to this rule is to write all the data in a programming block within one write cycle. The programming methods specified in this document comply with this requirement.

Note: A program memory word can be programmed twice before an erase, but only if (a) the same data is used in both program operations or (b) bits containing '1' are set to '0' but no '0' is set to '1'.

2.3 Memory Map

The program memory map extends from 0x0 to 0xFFFFFE. Code storage is located at the base of the memory map and supports up to 175,104 instructions (about 512 Kbytes). Table 2-2 shows the program memory size and number of erase and program blocks present in each device variant. Each erase block or page contains 1024 instructions and each program block or row, contains 128 instructions.

An additional 24 Kbytes of program Flash memory is available at locations 0x7FC000 through 0x7FFFFF, which is called auxiliary program Flash memory.

Locations 0x800000 through 0x800FFE are reserved for executive code memory. This region stores the programming executive and the debugging executive. The programming executive is used for device programming and the debug executive is used for in-circuit debugging. This region of memory cannot be used to store user code.

Locations 0xF80000 through 0xF80013 are reserved for the device Configuration registers.

Locations 0xFF0000 and 0xFF0002 are reserved for the Device ID Word registers. These bits can be used by the programmer to identify which device type is being programmed. They are described in **Section 8.0** "**Device ID**". The Device ID registers read out normally, even after code protection is applied.

Figure 2-2 shows the memory map for the dsPIC33E/PIC24E family variants.

TABLE 2-2: CODE MEMORY SIZE

3.0 DEVICE PROGRAMMING – ENHANCED ICSP

This section discusses programming the device through Enhanced ICSP and the programming executive. The programming executive resides in executive memory (separate from code memory) and is executed when Enhanced ICSP Programming mode is entered. The programming executive provides the mechanism for the programmer (host device) to program verify the dsPIC33E/PIC24E and Programming Specification family devices using a simple command set and communication protocol. There are several basic functions provided by the programming executive:

- Read Memory
- · Erase Memory
- Program Memory
- Blank Check
- Read Executive Firmware Revision

The programming executive performs the low-level tasks required for erasing, programming and verifying a device. This allows the programmer to program the device by issuing the appropriate commands and data. Table 3-1 summarizes the commands. A detailed description for each command is provided in Section 5.2 "Programming Executive Commands".

TABLE 3-1: COMMAND SET SUMMARY

Command	Description
SCHECK	Sanity check.
READC	Read Configuration registers or Device ID registers.
READP	Read primary Flash or auxiliary Flash memory.
PROGC	Program a Configuration register and verify.
PROGP	Program one row of code memory and verify.
ERASEB	Bulk Erase the device.
ERASEBP	Erase entire primary program Flash memory.
ERASEBA	Erase entire auxiliary Flash memory.
ERASEP	Erase Page command.
CRCP	Performs CRC on memory.
QBLANK	Query to check whether code memory is blank.
QVER	Query the software version.

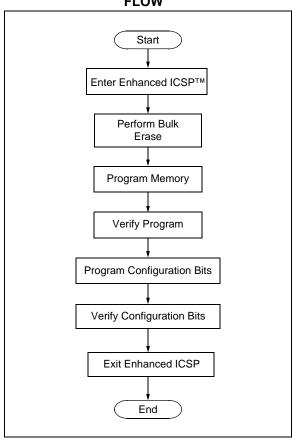

The programming executive uses the device's data RAM for variable storage and program execution. After the programming executive is run, no assumptions should be made about the contents of data RAM.

3.1 Overview of the Programming Process

Figure 3-1 shows the high-level overview of the programming process. After entering Enhanced ICSP mode, the programming executive is verified. Next, the device is erased, and then, the program Flash memory (primary and auxiliary Flash memory) is programmed, followed by the non-volatile device Configuration registers. Code memory (including the Configuration registers) is then verified to ensure that programming was successful.

After the programming executive has been verified in memory (or loaded if not present), the dsPIC33E/PIC24E Programming Specification can be programmed using the command set shown in Table 3-1.

FIGURE 3-1: HIGH-LEVEL ENHANCED ICSP™ PROGRAMMING FLOW

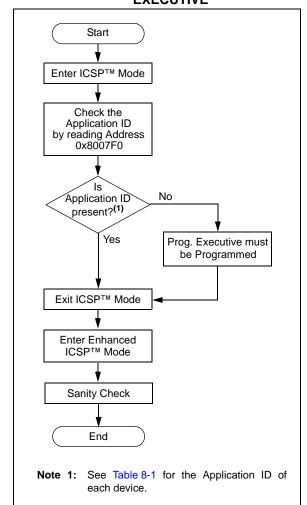

3.2 Confirming the Presence of the Programming Executive

Before programming, the programmer must confirm that the programming executive is stored in executive memory. The procedure for this task is shown in Figure 3-2.

First, ICSP mode is entered. Then, the unique Application ID Word stored in executive memory is read. If the programming executive is resident, the correct Application ID Word is read and programming can resume as normal. However, if the Application ID Word is not present, the programming executive must be programmed to executive code memory using the method described in Section 7.0 "Programming the Programming Executive to Memory". See Table 8-1 for the Application ID of each device.

Section 6.0 "Device Programming – ICSP" describes the ICSP programming method. Section 6.11 "Reading the Application ID Word" describes the procedure for reading the Application ID Word in ICSP mode.

FIGURE 3-2: CONFIRMING PRESENCE OF PROGRAMMING EXECUTIVE

3.3 Entering Enhanced ICSP Mode

As shown in Figure 3-3, entering Enhanced ICSP Program/Verify mode requires three steps:

- 1. The $\overline{\text{MCLR}}$ pin is briefly driven high then low.
- 2. A 32-bit key sequence is clocked into PGD.
- 3. MCLR is then driven high within a specified period of time and held.

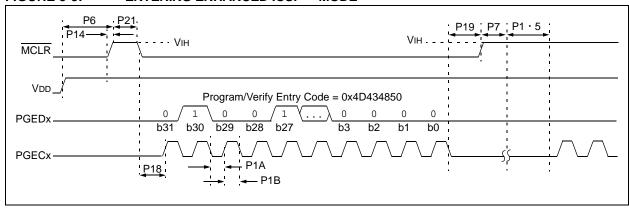

The programming voltage applied to MCLR is VIH, which is essentially VDD in case of dsPIC33E/PIC24E devices. There is no minimum time requirement for holding at VIH. After VIH is removed, an interval of at least P18 must elapse before presenting the key sequence on PGD.

The key sequence is a specific 32-bit pattern, '0100 1101 0100 0011 0100 1000 0101 0000' (more easily remembered as 0x4D434850 in hexadecimal format). The device will enter Program/ Verify mode only if the key sequence is valid. The Most Significant bit (MSb) of the most significant nibble must be shifted in first.

Once the <u>key</u> sequence is complete, VIH must be applied to MCLR and held at that level for as long as Program/Verify mode is to be maintained. An interval time of at least P19, P7, and P1*5 must elapse before presenting data on PGD. Signals appearing on PGD before this time has elapsed will not be interpreted as valid.

On successful entry, the program memory can be accessed and programmed in serial fashion. While in the Program/Verify mode, all unused I/Os are placed in the high-impedance state.

FIGURE 3-3: ENTERING ENHANCED ICSP™ MODE

3.4 Blank Check

The term "Blank Check" implies verifying that the device has been successfully erased and has no programmed memory locations. A blank or erased memory location is always read as '1', except for the GSSK<1:0> and APLK<1:0> bits in the FGS and FAS Configuration registers, which read as '0' when in a blank (erased) state.

The Device ID registers (0xFF0000:0xFF0002) can be ignored by the Blank Check since this region stores device information that cannot be erased. The device Configuration registers are also ignored by the Blank Check. Additionally, all unimplemented memory space should be ignored from the Blank Check.

The QBLANK command is used for the Blank Check. It determines if the code memory is erased by testing these memory regions. A 'BLANK' or 'NOT BLANK' response is returned. If it is determined that the device is not blank, it must be erased before attempting to program the chip.

3.5 Code Memory Programming

3.5.1 PROGRAMMING METHODOLOGY

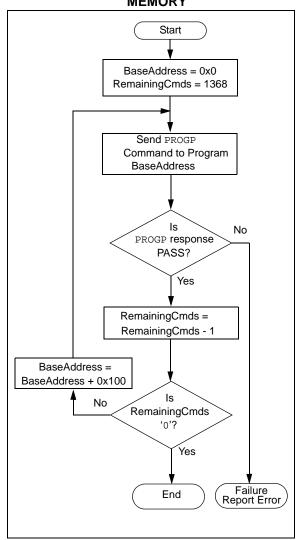

Code memory (primary or auxiliary Flash) is programmed with the PROGP command. PROGP programs one row of code memory starting from the memory address specified in the command. The number of PROGP commands required to program a device depends on the number of write blocks that must be programmed in the device.

A flowchart for programming code memory is shown in Figure 3-4. In this example, all 175,104 instruction words of a dsPIC33E/PIC24E device are programmed. First, the number of commands to send (called 'RemainingCmds' in the flowchart) is set to 1368 and the destination address (called 'BaseAddress') is set to '0'. Next, one write block in the device is programmed with a PROGP command. Each PROGP command contains data for one row of code memory of the dsPIC33E/PIC24E. After the first command is successfully, 'RemainingCmds' processed decremented by '1' and compared with '0'. Since there are more PROGP commands to send, 'BaseAddress' is incremented by 0x100 to point to the next row of memory.

On the second PROGP command, the second row is programmed. This process is repeated until the entire device is programmed.

Note: If a bootloader needs to be programmed, the bootloader code must not be programmed into the first page of code memory. For example, if a bootloader located at address 0x200 attempts to erase the first page, it would inadvertently erase itself. Instead, program the bootloader into the second page (e.g., 0x400).

FIGURE 3-4: FLOWCHART FOR PROGRAMMING CODE MEMORY

3.5.2 PROGRAMMING VERIFICATION

After code memory is programmed, the contents of memory can be verified to ensure that programming was successful. Verification requires code memory to be read back and compared against the copy held in the programmer's buffer.

The $\ensuremath{\mathtt{READP}}$ command can be used to read back all the programmed code memory.

Alternatively, you can have the programmer perform the verification after the entire device is programmed, using a checksum computation.

4.0 CHECKSUM COMPUTATION

Checksums for devices are 16 bits in size. The checksum is calculated by summing the following:

- · Contents of code memory locations
- · Contents of Configuration bytes

All memory locations are summed one byte at a time using only their native data size. Configuration bytes are summed by adding the lower byte of these locations (the upper bytes are ignored), while code memory is summed by adding all three bytes of code memory.

Table 4-1 is an example of the checksum calculation for the dsPIC33EP64MC506 device.

Table 4-2 describes the Configuration bit masks for each device.

TABLE 4-1: CHECKSUM COMPUTATION EXAMPLE

Device	Read Code Protection	Checksum Computation	Erased Value	Value with 0xAAAAAA at 0x0 and Last Code Address
dsPIC33EP256MU806	Disabled	CFGB ⁽³⁾ + SUM(0:0x02ABFF) + SUM(0x7FC000:0x7FFFFF)	0xA288	0x9E8C
	Enabled	CFGB ⁽³⁾	0x04E2	0x04E2

Item Description:

SUM(a:b) = Byte sum of locations a to b inclusive (all 3 bytes of code memory)

CFGB = Configuration Block (masked) = Byte sum of ((FGS & $0x33^{(1)}$) + (FOSCSEL & 0x87) + (FOSC & 0xE7) + (FWDT & 0xFF) + (FPOR & 0x3F) + (FICD & 0xF7) + (FAS & $0x33^{(2)}$) + (FUID0 & 0xFF))

- **Note 1:** For FGS, the read mask is 0x33; however, because of the General Segment Key bits, 0x03 is used with code protection disabled, and 0x30 is used with code protection enabled for the checksum calculations in Table 4-1.
 - 2: For FAS, the read mask is 0x33; however, because of the Auxiliary Segment Key bits, 0x03 is used with code protection disabled, and 0x30 is used with code protection enabled for the checksum calculations in Table 4-1.
 - **3:** For the checksum computation example the configuration bits are set to the recommended default value shown in Table 6-6.

4.1 Configuration Bits Programming

4.1.1 OVERVIEW

The dsPIC33E/PIC24E devices have Configuration bits stored in eight 8-bit Configuration registers, aligned on even configuration memory address boundaries. These bits can be set or cleared to select various device configurations. There are three types of Configuration bits: system operation bits, code-protect bits and unit ID bits. The system operation bits determine the power-on settings for system level

components, such as oscillator and Watchdog Timer. The code-protect bits prevent program memory from being read and written.

The register descriptions for the FGS, FOSCSEL, FOSC, FWDT, FPOR, FAS and FICD Configuration registers are shown in Table 4-3.

The Configuration register map is shown in Table 4-4.

Note 1: If any of the code-protect bits in FAS or FGS is clear, the entire device must be erased before it can be reprogrammed.

TABLE 4-3: dsPIC33E/PIC24E CONFIGURATION BITS DESCRIPTION

Bit Field	Register	Description
GSSK<1:0>	FGS	General Segment Key bits. These bits must be set to '00' if GWRP = 1 and GSS = 1. These bits must be set to '11' for any other value of the GWRP and GSS bits. Any mismatch between either the GWRP or GSS bits, and the GSSK bits (as described above), will result in a locked device. A Flash bulk erase will be required to unlock the device.
GSS	FGS	General Segment Code-Protect bit 1 = User program memory is not code-protected 0 = User program memory is code-protected
GWRP	FGS	General Segment Write-Protect bit 1 = User program memory is not write-protected 0 = User program memory is write-protected
IESO	FOSCSEL	Two-speed Oscillator Start-up Enable bit 1 = Start-up device with FRC, then automatically switch to the user-selected oscillator source when ready 0 = Start-up device with user-selected oscillator source
FNOSC<2:0>	FOSCSEL	Initial Oscillator Source Selection bits 111 = Internal Fast RC (FRC) oscillator with postscaler 110 = Internal Fast RC (FRC) oscillator with divide-by-16 101 = LPRC oscillator 100 = Secondary (LP) oscillator 011 = Primary (XT, HS, EC) oscillator with PLL 010 = Primary (XT, HS, EC) oscillator 001 = Internal Fast RC (FRC) oscillator with PLL 000 = FRC oscillator
FCKSM<1:0>	FOSC	Clock Switching Mode bits 1x = Clock switching is disabled, Fail-Safe Clock Monitor is disabled 01 = Clock switching is enabled, Fail-Safe Clock Monitor is disabled 00 = Clock switching is enabled, Fail-Safe Clock Monitor is enabled
IOL1WAY	FOSC	Peripheral pin select configuration 1 = Allow only one reconfiguration 0 = Allow multiple reconfigurations
OSCIOFNC	FOSC	OSC2 Pin Function bit (except in XT and HS modes) 1 = OSC2 is clock output 0 = OSC2 is general purpose digital I/O pin
POSCMD<1:0>	FOSC	Primary Oscillator Mode Select bits 11 = Primary oscillator disabled 10 = HS Crystal Oscillator mode 01 = XT Crystal Oscillator mode 00 = EC (External Clock) mode

Note 1: This bit is not available on dsPIC33EP256MU806 (64-pin) devices.

TABLE 4-3: dsPIC33E/PIC24E CONFIGURATION BITS DESCRIPTION (CONTINUED)

Bit Field	Register	Description
FWDTEN	FWDT	Watchdog Timer Enable bit 1 = Watchdog Timer always enabled (LPRC oscillator cannot be disabled. Clearing the SWDTEN bit in the RCON register has no effect.) 0 = Watchdog Timer enabled/disabled by user software (LPRC can be disabled by clearing the SWDTEN bit in the RCON register)
WINDIS	FWDT	Watchdog Timer Window Enable bit 1 = Watchdog Timer in Non-Window mode 0 = Watchdog Timer in Window mode
PLLKEN	FWDT	PLL Lock Wait Enable bit 1 = Clock switches to the PLL source will wait until the PLL lock signal is valid 0 = Clock switch will not wait for PLL lock
WDTPRE	FWDT	Watchdog Timer Prescaler bit 1 = 1:128 0 = 1:32
WDTPOST<3:0>	FWDT	Watchdog Timer Postscaler bits 1111 = 1:32,768 1110 = 1:16,384
APLK<1:0>	FAS	Auxiliary Segment Key bits These bits must be set to '00' if AWRP = 1 and APL = 1. These bits must be set to '11' for any other value of the AWRP and APL bits. Any mismatch between either the AWRP or APL bits, and the APLK bits (as described above), will result in a locked device. A Flash bulk erase will be required to unlock the device.
APL	FAS	Auxiliary Segment Code-protect bit 1 = Auxiliary program memory is not code-protected 0 = Auxiliary program memory is code-protected
AWRP	FAS	Auxiliary Segment Write-protect bit 1 = Auxiliary program memory is not write-protected 0 = Auxiliary program memory is write-protected
FPWRT<2:0>	FPOR	Power-on Reset Timer Value Select bits 111 = PWRT = 128 ms 110 = PWRT = 64 ms 101 = PWRT = 32 ms 100 = PWRT = 16 ms 011 = PWRT = 8 ms 010 = PWRT = 4 ms 001 = PWRT = 2 ms 000 = PWRT = Disabled
BOREN	FPOR	Brown-out Reset (BOR) Detection Enable bit 1 = BOR is enabled 0 = BOR is disabled
ALTI2C2 ⁽¹⁾	FPOR	Alternate I ² C TM pins for I2C2 1 = I2C2 mapped to SDA2/SCL2 pins 0 = I2C2 mapped to ASDA2/ASCL2 pins
ALTI2C1	FPOR	Alternate I ² C pins for I2C1 1 = I2C1 mapped to SDA1/SCL1 pins 0 = I2C1 mapped to ASDA1/ASCL1 pins

Note 1: This bit is not available on dsPIC33EP256MU806 (64-pin) devices.

TABLE 4-3: dsPIC33E/PIC24E CONFIGURATION BITS DESCRIPTION (CONTINUED)

Bit Field	Register	Description
JTAGEN	FICD	JTAG Enable bit
		1 = JTAG enabled 0 = JTAG disabled
RSTPRI	FICD	Reset Target Vector Select bit
		1 = Device will execute code from primary Flash memory on a reset 0 = Device will execute code from auxiliary Flash memory on a reset
ICS<1:0>	FICD	ICD Communication Channel Select bits
		11 = Communicate on PGEC1 and PGED1 10 = Communicate on PGEC2 and PGED2 01 = Communicate on PGEC3 and PGED3
		00 = Reserved, do not use

Note 1: This bit is not available on dsPIC33EP256MU806 (64-pin) devices.

0xF80010	FAS	_	_	APLK	<1:0>	_	_	APL	AWRP
0xF80012	FUID0	User Unit ID Byte 0							

Legend: — = unimplemented bit, read as '0'

Note 1: These bits are reserved for use by development tools and must be programmed as '1'.

2: These bits are reserved on dsPIC33EP256MU806 (64-pin) devices and always read as '1'.

4.1.2 PROGRAMMING METHODOLOGY

Configuration bits may be programmed a single byte at a time using the PROGC command. This command specifies the configuration data and Configuration register address.

Eight PROGC commands are required to program all the Configuration bits. A flowchart for Configuration bit programming is shown in Figure 4-1.

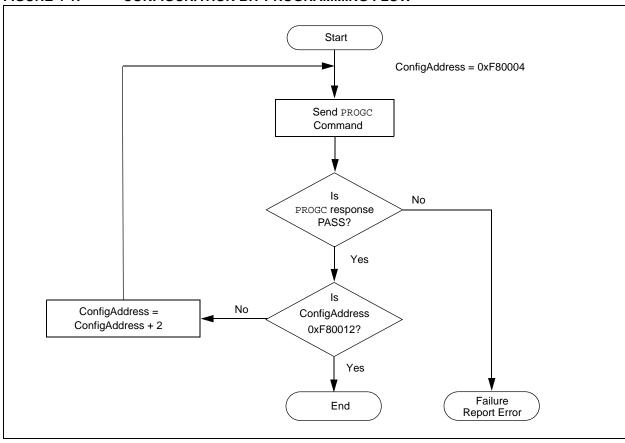

Note: the General Code Segment Code-Protect bit (GSS) is programmed to '0', code memory is code-protected and cannot be read. Code memory must verified before enabling read Section 4.1.4 protection. See "CodeGuard™ Security Configuration Bits" for detailed information about code-protect Configuration bits.

4.1.3 PROGRAMMING VERIFICATION

After the Configuration bits are programmed, the contents of memory should be verified to ensure that the programming was successful. Verification requires the Configuration bits to be read back and compared against the copy held in the programmer's buffer. The READC command reads back the programmed Configuration bits and verifies that the programming was successful.

Any unimplemented Configuration bits are read-only and read as '0'. The reserved bits are read-only and read as '1'.

FIGURE 4-1: CONFIGURATION BIT PROGRAMMING FLOW

4.1.4 CodeGuard™ SECURITY CONFIGURATION BITS

The FGS and FAS Configuration registers are special Configuration registers that control the level of code protection for the General Segment (user code memory) and auxiliary Flash memory, respectively. For each of these memory regions, two main forms of code protection are provided. One form prevents code memory from being written (write protection), while the other prevents code memory from being read (read protection).

The GWRP and AWRP bits control write protection and the GSS and APL bits control read protection. The Chip Erase ERASEB command sets these four code protection bits to '1', which allows the device to be programmed.

When write protection is enabled, any programming operation to code memory will fail. When read protection is enabled, any read from code memory will cause a '0x0' to be read, regardless of the actual contents of code memory. Since the programming executive always verifies what it programs, attempting to program code memory with read protection enabled will also result in failure.

It is imperative that all of the previously described code protection bits are '1' while the device is being programmed and verified. Only after the device is programmed and verified should any of the above bits be programmed to '0'.

Note:

All code-protect/write-protect bits in the FAS and FGS Configuration registers can only be programmed to a value of '0'. the ERASEB command is the only way to reprogram code-protect bits from ON ('0') to OFF ('1').

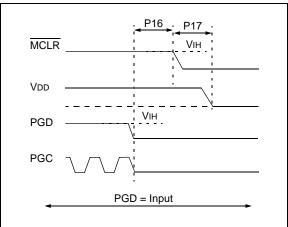

4.1.5 BENEFIT OF USER UNIT ID

The dsPIC33E/PIC24E devices provide an 8-bit Configuration register (FUID0) for the user to store product-specific information, such as unit serial numbers and other product manufacturing data.

4.2 Exiting Enhanced ICSP Mode

Exiting Program/Verify mode is done by removing VIH from MCLR, as shown in Figure 4-2. The only requirement for exit is that an interval P16 should elapse between the last clock and program signals on PGC and PGD before removing VIH.

FIGURE 4-2: EXITING ENHANCED ICSPTM MODE

5.0 THE PROGRAMMING EXECUTIVE

Note:

The Programming Executive (PE) can be located within the following folder within your installation of MPLAB® IDE:

...\Microchip\MPLAB IDE\REAL ICE, and then selecting the hex PE file, RIPE_10_xxxxxx.hex (where xxxxxx is the version number).

5.1 Programming Executive Communication

The programmer and programming executive have a master-slave relationship, where the programmer is the master programming device and the programming executive is the slave.

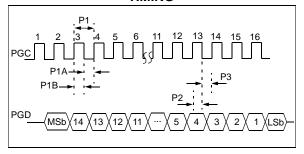

All communication is initiated by the programmer in the form of a command. Only one command at a time can be sent to the programming executive. In turn, the programming executive only sends one response to the programmer after receiving and processing a command. The programming executive command set is described in Section 5.2 "Programming Executive Commands". The response set is described in Section 5.3 "Programming Executive Responses".

5.1.1 COMMUNICATION INTERFACE AND PROTOCOL

The ICSP/Enhanced ICSP interface is a 2-wire SPI implemented using the PGC and PGD pins. The PGC pin is used as a clock input pin and the clock source must be provided by the programmer. The PGD pin is used for sending command data to and receiving response data from the programming executive.

Note: For Enhanced ICSP, all serial data is transmitted on the falling edge of PGC and latched on the rising edge of PGC. All data transmissions are sent to the Most Significant bit first using 16-bit mode (see Figure 5-1).

FIGURE 5-1: PROGRAMMING EXECUTIVE SERIAL TIMING

Since a 2-wire SPI is used, and data transmissions are bidirectional, a simple protocol is used to control the direction of PGD. When the programmer completes a command transmission, it releases the PGD line and allows the programming executive to drive this line high. The programming executive keeps the PGD line high to indicate that it is processing the command.

After the programming executive has processed the command, it brings PGD low (P9b) to indicate to the programmer that the response is available to be clocked out. The programmer can begin to clock out the response after maximum wait (P9b) and it must provide the necessary amount of clock pulses to receive the entire response from the programming executive.

After the entire response is clocked out, the programmer should terminate the clock on PGC until it is time to send another command to the programming executive. This protocol is shown in Figure 5-2.

5.1.2 SPI RATE

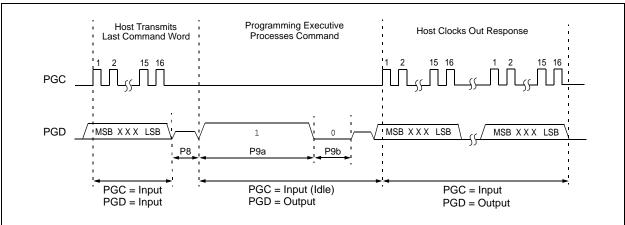

In Enhanced ICSP mode, the dsPIC33E/PIC24E family devices operate from the Fast Internal RC oscillator, which has a nominal frequency of 7.3728 MHz. This oscillator frequency yields an effective system clock frequency of 3.6864 MHz. To ensure that the programmer does not clock too fast, it is recommended that a 1.8432 MHz clock be provided by the programmer.

5.1.3 TIME OUTS

The programming executive uses no Watchdog or time out for transmitting responses to the programmer. If the programmer does not follow the flow control mechanism using PGC as described in **Section 5.1.1** "Communication Interface and Protocol", it is possible that the programming executive will behave unexpectedly while trying to send a response to the programmer. Since the programming executive has no time out, it is imperative that the programmer correctly follow the described communication protocol.

As a safety measure, the programmer should use the command time outs identified in Table 5-1. If the command time out expires, the programmer should reset the programming executive and start programming the device again.

5.2 Programming Executive Commands

The programming executive command set is shown in Table 5-1. This table contains the opcode, mnemonic, length, time out and description for each command. Functional details on each command are provided in the command descriptions (Section 5.2.4 "Command Descriptions").

5.2.1 COMMAND FORMAT

All programming executive commands have a general format consisting of a 16-bit header and any required data for the command (see Figure 5-3). The 16-bit header consists of a 4-bit opcode field, which is used to identify the command, followed by a 12-bit command length field.

FIGURE 5-3: COMMAND FORMAT

11	0				
Length					
Command Data First Word (if required)					
•					
•					
Command Data Last Word (if required)					
	nand Data First Word (if required) • •				

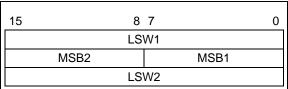

The command opcode must match one of those in the command set. Any command that is received which does not match the list in Table 5-1 will return a "NACK" response (see Section 5.3.1.1 "opcode Field").

The command length is represented in 16-bit words since the SPI operates in 16-bit mode. The programming executive uses the command length field to determine the number of words to read from the SPI port. If the value of this field is incorrect, the command will not be properly received by the programming executive.

5.2.2 PACKED DATA FORMAT

When 24-bit instruction words are transferred across the 16-bit SPI interface, they are packed to conserve space using the format shown in Figure 5-4. This format minimizes traffic over the SPI and provides the programming executive with data that is properly aligned for performing table write operations.

FIGURE 5-4: PACKED INSTRUCTION WORD FORMAT

LSWx: Least Significant 16 bits of instruction word MSBx: Most Significant Byte of instruction word

Note: When the number of instruction words transferred is odd, MSB2 is zero and LSW2 can not be transmitted.

5.2.3 PROGRAMMING EXECUTIVE ERROR HANDLING

The programming executive will "NACK" all unsupported commands. Additionally, due to the memory constraints of the programming executive, no checking is performed on the data contained in the programmer command. It is the responsibility of the programmer to command the programming executive with valid command arguments or the programming operation may fail. Additional information on error handling is provided in **Section 5.3.1.3** "QE_Code **Field**".

TABLE 5-1: PROGRAMMING EXECUTIVE COMMAND SET

Opcode	Mnemonic	Length (16-bit words)	Time Out	Description
0x0	SCHECK	1	1 ms	Sanity check.
0x1	READC	3	1 ms	Read an 8-bit word from the specified Configuration register or Device ID register.
0x2	READP	4	1 ms/row	Read 'N' 24-bit instruction words of primary or auxiliary Flash memory starting from the specified address.
0x3	Reserved	N/A	N/A	This command is reserved. It will return a NACK.
0x4	PROGC	4	5 ms	Write an 8-bit word to the specified Configuration register.
0x5	PROGP	195	5 ms	Program one row of primary or auxiliary Flash memory at the specified address, then verify.
0x6	ERASEBP	1	75 ms	Erase entire primary Flash memory and FGS register.
0x7	ERASEB	1	125 ms	Bulk Erase the device.
0x8	ERASEBA	1	75 ms	Erase entire auxiliary Flash memory and FAS register.
0x9	ERASEP	3	25 ms	Command to erase a page.
0xA	Reserved	N/A	N/A	This command is reserved. It will return a NACK.
0xB	QVER	1	1 ms	Query the programming executive software version.
0xC	CRCP	5	1s	Performs a CRC-16 on the specified range of memory.
0xD	Reserved	N/A	N/A	This command is reserved. It will return a NACK.
0xE	QBLANK	5	700 ms	Query to check whether the code memory is blank.

Note: One row of code memory consists of (64) 24-bit words. Refer to Table 2-2 for device-specific information.

5.2.4 COMMAND DESCRIPTIONS

All commands supported by the programming executive are described in **Section 5.2.5** "SCHECK Command" through **Section 5.2.16** "QVER Command".

5.2.5 SCHECK COMMAND

15	5 12	11 0
	Opcode	Length

Field	Description
Opcode	0x0
Length	0x1

The SCHECK command instructs the programming executive to do nothing but generate a response. This command is used as a "Sanity Check" to verify that the programming executive is operational.

Expected Response (2 words):

0x1000 0x0002

Note:	This	instructio	n is	not	required	for
	programming,		but	is	provided	for
	devel	opment pu	ırpose	es onl	у.	

5.2.6 READC COMMAND

15 12	11 8	7	0
Opcode		Length	
1	١	Addr_MSB	
Addr_		LS	

Field	Description
Opcode	0x1
Length	0x3
N	Number of 8-bit Configuration registers or Device ID registers to read (maximum of 256).
Addr_MSB	MSB of 24-bit source address.
Addr_LS	Least Significant 16 bits of 24-bit source address.

The READC command instructs the programming executive to read N Configuration registers or Device ID registers, starting from the 24-bit address specified by Addr_MSB and Addr_LS. This command can only be used to read 8-bit or 16-bit data.

When this command is used to read Configuration registers, the upper byte in every data word returned by the programming executive is 0x00 and the lower byte contains the Configuration register value.

Expected Response (4 + 3 * (N - 1)/2 words for N odd):

0x1100

2 + N

Configuration register or Device ID Register 1

...

Configuration register or Device ID Register N

Note:	Reading unimplemented memory will
	cause the programming executive to
	reset. Please ensure that only memory
	locations present on a particular device
	are accessed.

5.2.7 READP COMMAND

15 12	11 8	/	U
Opcode		Length	
	N		
Rese	rved	Addr_MSB	
	Addr_	LS	

Field	Description
Opcode	0x2
Length	0x4
N	Number of 24-bit instructions to read (maximum of 32768).
Reserved	0x0
Addr_MSB	MSB of 24-bit source address.
Addr_LS	Least Significant 16 bits of 24-bit source address.

The READP command instructs the programming executive to read N 24-bit words of code memory, starting from the 24-bit address specified by Addr_MSB and Addr_LS. This command can only be used to read 24-bit data. All data returned in the response to this command uses the packed data format described in Section 5.2.2 "Packed Data Format".

Expected Response (2 + 3 * N/2 words for N even):

0x1200

2 + 3 * N/2

Least significant program memory word 1

...

Least significant data word N

Expected Response (4 + 3 * (N - 1)/2 words) for N odd):

0x1200

4 + 3 * (N - 1)/2

Least significant program memory word 1

...

MSB of program memory word N (zero padded)

Note:	Reading unimplemented memory will
	cause the programming executive to
	reset. Please ensure that only memory
	locations present on a particular device
	are accessed.

15

5.2.8 PROGC COMMAND

15	12	11	8	7		0
Opo	code			Le	ength	
	Rese	rved			Addr_MSB	
			Addr_	LS		
			Data	a	_	•

Field	Description
Opcode	0x4
Length	0x4
Reserved	0x0
Addr_MSB	MSB of 24-bit destination address.
Addr_LS	Least Significant 16 bits of 24-bit destination address.
Data	8-bit data word.

The PROGC command instructs the programming executive to program a single Configuration register, located at the specified memory address.

After the specified data word has been programmed to code memory, the programming executive verifies the programmed data against the data in the command.

Expected Response (2 words):

0x1400 0x0002

5.2.9 PROGP COMMAND

12 11

15	12	11	0	1		U
Opc	ode			Ler	ngth	
	Rese	rved			Addr_MSB	
			Addr_	LS		
	D_1					
	D_2					
	•					
			D_1	N		

8 7

Λ

Field	Description	
Opcode	0x5	
Length	0x63	
Reserved	0x0	
Addr_MSB	MSB of 24-bit destination address.	
Addr_LS	Least Significant 16 bits of 24-bit destination address.	
D_1	16-bit data word 1.	
D_2	16-bit data word 2.	
	16-bit data word 3 through 191.	
D_192	16-bit data word 192.	

The PROGP command instructs the programming executive to program one row of code memory (128 instruction words) to the specified memory address. Programming begins with the row address specified in the command. The destination address should be a multiple of 0x100.

The data to program the memory, located in command words D_1 through D_192, must be arranged using the packed instruction word format shown in Figure 5-4.

After all data has been programmed to code memory, the programming executive verifies the programmed data against the data in the command.

Expected Response (2 words):

0x1500 0x0002

Note: Refer to Table 2-2 for code memory size information.

5.2.10 ERASEB COMMAND

15	12	11		0
Opco	de		Length	

Field	Description	
Opcode	0x7	
Length	0x1	

The ERASEB command instructs the programming executive to perform a Bulk Erase (i.e., erase all of the primary Flash memory, auxiliary Flash memory, executive memory and code-protect bits).

Expected Response (2 words):

0x1700

0x0002

5.2.11 ERASEBP COMMAND

15 12	11 0
Opcode	Length

Field	Description	
Opcode	0x6	
Length	0x1	

The ERASEBP command instructs the programming executive to perform a Bulk Erase (i.e., erase all of the primary Flash memory and the FGS register).

Expected Response (2 words):

0x1600

0x0002

5.2.12 ERASEBA COMMAND

15 12	11 0
Opcode	Length

Field	Description
Opcode	0x8
Length	0x1

The ERASEBA command instructs the programming executive to perform a Bulk Erase (i.e., erase all of the auxiliary Flash memory and the FAS register).

Expected Response (2 words):

0x1800

0x0002

5.2.13 ERASEP COMMAND

15 12	11 0	1	U
Opcode		Length	
NUM_P	AGES	Addr_MSB	

Addr_LS

Field	Description
Opcode	0x9
Length	0x3
NUM_PAGES	Up to 255
Addr_MSB	Most Significant Byte of the 24-bit address
Addr_LS	Least Significant 16-bits of the 24-bit

The ERASEP command instructs the programming executive to page erase [NUM_PAGES] of code memory. The code memory must be erased at an "even" 1024 instruction word address boundary

Expected Response (2 words):

0x1900

0x0002

5.2.14 CRCP COMMAND

15 12 11 8 7 0

Opcode		Length
Reserved Addr_MSB		Addr_MSB
Addr_LSW		
Reserved Size_MSB		Size_MSB
Size_LSW		

Field	Description
Opcode	0xC
Length	0x5
Addr_MSB	Most Significant Byte of 24-bit address
Addr_LSW	Least Significant 16-bits of 24-bit address
Size	Number of 24-bit locations (address range divided by 2)

The CRCP command performs a CRC-16 on the range of memory specified. This command can substitute for a full chip verify. Data is shifted in a packed method as demonstrated in Figure 5-4, byte-wise Least Significant Byte (LSB) first.

Example:

CRC-CCITT-16 with test data of "123456789" becomes 0x29B1

Expected Response (3 words):

QE_Code: 0x1C00 Length: 0x0003 CRC Value: 0xXXXX

5.2.15 QBLANK COMMAND

 15
 12
 11
 0

 Opcode
 Length

 Reserved
 Size_MSB

 Size_LSW

 Reserved
 Addr_MSB

Addr_LSW

Field	Description
Opcode	0xE
Length	0x5
Size	Length of program memory to check (in 24-bit words) + Addr_MS
Addr_MSB	Most Significant Byte of the 24-bit address
Addr_LSW	Least Significant 16-bits of the 24-bit address

The QBLANK command queries the programming executive to determine if the contents of code memory are blank (contains all '1's). The size of code memory to check must be specified in the command.

The Blank Check for code memory begins at [Addr] and advances toward larger addresses for the specified number of instruction words.

QBLANK returns a QE_Code of 0xF0 if the specified code memory is blank; otherwise, QBLANK returns a QE_Code of 0x0F.

Expected Response (2 words for blank device):

0x1DF0 0x0002

Expected Response (2 words for non-blank device):

0x1D0F 0x0002

Note:	The QBLANK command does not check
	the system operation Configuration bits
	since these bits are not set to '1' when a
	Chip Frase is performed.

5.2.16 OVER COMMAND

15 12	11 0
Opcode	Length

Field	Description
Opcode	0xB
Length	0x1

The QVER command queries the version of the programming executive software stored in test memory. The "version.revision" information is returned in the response's QE_Code using a single byte with the following format: main version in upper nibble and revision in the lower nibble (i.e., 0x23 means version 2.3 of programming executive software).

Expected Response (2 words):

0x1BMN (where "MN" stands for version M.N) 0x0002

5.3 Programming Executive Responses

The programming executive sends a response to the programmer for each command that it receives. The response indicates if the command was processed correctly. It includes any required response data or error data.

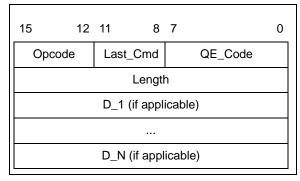

The programming executive response set is shown in Table 5-2. This table contains the opcode, mnemonic and description for each response. The response format is described in **Section 5.3.1** "Response Format".

TABLE 5-2: PROGRAMMING EXECUTIVE RESPONSE OPCODES

Opcode	Mnemonic	Description
0x1	PASS	Command successfully processed.
0x2	FAIL	Command unsuccessfully processed.
0x3	NACK	Command not known.

5.3.1 RESPONSE FORMAT

All programming executive responses have a general format consisting of a two-word header and any required data for the command.

Field	Description
Opcode	Response opcode.
Last_Cmd	Programmer command that generated the response.
QE_Code	Query code or error code.
Length	Response length in 16-bit words (includes 2 header words).
D_1	First 16-bit data word (if applicable).
D_N	Last 16-bit data word (if applicable).

5.3.1.1 Opcode Field

The opcode is a 4-bit field in the first word of the response. The opcode indicates how the command was processed (see Table 5-2). If the command was processed successfully, the response opcode is PASS. If there was an error in processing the command, the response opcode is FAIL and the QE_Code indicates the reason for the failure. If the command sent to the programming executive is not identified, the programming executive returns a NACK response.

5.3.1.2 Last_Cmd Field

The Last_Cmd is a 4-bit field in the first word of the response and indicates the command that the programming executive processed. Since the programming executive can only process one command at a time, this field is technically not required. However, it can be used to verify that the programming executive correctly received the command that the programmer transmitted.

5.3.1.3 QE Code Field

The QE_Code is a byte in the first word of the response. This byte is used to return data for query commands and error codes for all other commands.

When the programming executive processes one of the two query commands (QBLANK or QVER), the returned opcode is always PASS and the QE_Code holds the query response data. The format of the QE_Code for both queries is shown in Table 5-3.

TABLE 5-3: QE Code FOR QUERIES

Query	QE_Code
QBLANK	0x0F = Code memory is NOT blank 0xF0 = Code memory is blank
QVER	0xMN, where programming executive software version = M.N (i.e., 0x32 means software version 3.2).

When the programming executive processes any command other than a Query, the QE_Code represents an error code. Supported error codes are shown in Table 5-4. If a command is successfully processed, the returned QE_Code is set to 0x0, which indicates that there is no error in the command processing. If the verify of the programming for the PROGP or PROGC command fails, the QE_Code is set to 0x1. For all other programming executive errors, the QE_Code is 0x2.

TABLE 5-4: QE_Code FOR NON-QUERY COMMANDS

QE_Code	Description
0x0	No error.
0x1	Verify failed.
0x2	Other error.

5.3.1.4 Response Length

The response length indicates the length of the programming executive's response in 16-bit words. This field includes the 2 words of the response header.

With the exception of the response for the READP command, the length of each response is only 2 words.

The response to the READP command uses the packed instruction word format described in **Section 5.2.2** "Packed Data Format". When reading an odd number of program memory words (N odd), the response to the READP command is (3 * (N + 1)/2 + 2) words. When reading an even number of program memory words (N even), the response to the READP command is (3 * N/2 + 2) words.

6.0 DEVICE PROGRAMMING – ICSP

ICSP mode is a special programming protocol that allows you to read and write to dsPIC33E/PIC24E device family memory. The ICSP mode is the most direct method used to program the device; however, note that Enhanced ICSP is faster. ICSP mode also has the ability to read the contents of executive memory to determine if the programming executive is present. This capability is accomplished by applying control codes and instructions serially to the device using pins PGC and PGD.

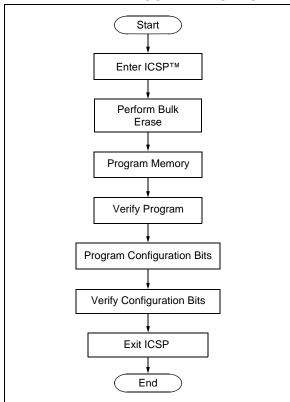

In ICSP mode, the system clock is taken from the PGC pin, regardless of the device's oscillator Configuration bits. All instructions are shifted serially into an internal buffer, then loaded into the instruction register and executed. No program fetching occurs from internal memory. Instructions are fed in 24 bits at a time. PGD is used to shift data in, and PGC is used as both the serial shift clock and the CPU execution clock.

Note: During ICSP operation, the operating frequency of PGC must not exceed 5 MHz.

6.1 Overview of the Programming Process

Figure 6-1 shows the high-level overview of the programming process. After entering ICSP mode, the first action is to Bulk Erase the device. Next, the code memory is programmed, followed by the device Configuration registers. Code memory (including the Configuration registers) is then verified to ensure that programming was successful. Then, program the code-protect Configuration bits, if required.

FIGURE 6-1: HIGH-LEVEL ICSP™ PROGRAMMING FLOW

6.2 Entering ICSP Mode

As shown in Figure 6-5, entering ICSP Program/Verify mode requires three steps:

- 1. MCLR is briefly driven high then low (P21)⁽¹⁾.
- 2. A 32-bit key sequence is clocked into PGD.
- MCLR is then driven high within a specified period of time and held.

Note 1: The MCLR capacitor value can vary the high time required for entering ICSP mode.

The programming voltage applied to MCLR is VIH, which is essentially VDD in the case of dsPIC33E/PIC24E devices. There is no minimum time requirement for holding at VIH. After VIH is removed, an interval of at least P18 must elapse before presenting the key sequence on PGD.

The key sequence is a specific 32-bit pattern, '0100 1101 0100 0011 0100 1000 0101 0001' (more easily remembered as 0x4D434851 in hexadecimal). The device will enter Program/Verify mode only if the sequence is valid. The Most Significant bit of the most significant nibble must be shifted in first.

Once the key sequence is complete, VIH must be applied to MCLR and held at that level for as long as Program/Verify mode is to be maintained. An interval of at least time P19, P7, and P1*5 must elapse before presenting data on PGD. Signals appearing on PGD before this time has elapsed will not be interpreted as valid.

On successful entry, the program memory can be accessed and programmed in serial fashion. While in ICSP mode, all unused I/Os are placed in the high-impedance state.

6.3 ICSP Operation

After entering into ICSP mode, the CPU is Idle. Execution of the CPU is governed by an internal state machine. A 4-bit control code is clocked in using PGC and PGD and this control code is used to command the CPU (see Table 6-1).

The SIX control code is used to send instructions to the CPU for execution and the REGOUT control code is used to read data out of the device via the VISI register.

TABLE 6-1: CPU CONTROL CODES IN ICSP™ MODE

4-Bit Control Code	Mnemonic	Description
0000b	SIX	Shift in 24-bit instruction and execute.
0001b	REGOUT	Shift out the VISI register.
0010b-1111b	N/A	Reserved.

6.3.1 SIX SERIAL INSTRUCTION EXECUTION

The SIX control code allows execution of dsPIC33E/PIC24E Programming Specification assembly instructions. When the SIX code is received, the CPU is suspended for 24 clock cycles, as the instruction is then clocked into the internal buffer. Once the instruction is shifted in, the state machine allows it to be executed over the next four clock cycles. While the received instruction is executed, the state machine simultaneously shifts in the next 4-bit command (see Figure 6-3).

- Note 1: Coming out of the ICSP entry sequence, the first 4-bit control code is always forced to SIX and a forced NOP instruction is executed by the CPU. Five additional PGC clocks are needed on start-up, thereby resulting in a 9-bit SIX command instead of the normal 4-bit SIX command. After the forced SIX is clocked in, ICSP operation resumes as normal (the next 24 clock cycles load the first instruction word to the CPU). See Figure 6-2 for details.
 - 2: TBLRDH and TBLRDL instructions must be followed by five NOP instructions. TBLWTH and TBLWTL instructions must be followed by two NOP instructions.

6.3.2 REGOUT SERIAL INSTRUCTION EXECUTION

The REGOUT control code allows for data to be extracted from the device in ICSP mode. It is used to clock the contents of the VISI register out of the device over the PGD pin. After the REGOUT control code is received, the CPU is held Idle for eight cycles. After these eight cycles, an additional 16 cycles are required to clock the data out (see Figure 6-4).

The REGOUT code is unique because the PGD pin is an input when the control code is transmitted to the device. However, after the control code is processed, the PGD pin becomes an output as the VISI register is shifted out.

Note: The device will latch input PGD data on the rising edge of PGC and will output data on the PGD line on the rising edge of PGC. For all data transmissions, the Least Significant bit (LSb) is transmitted first.

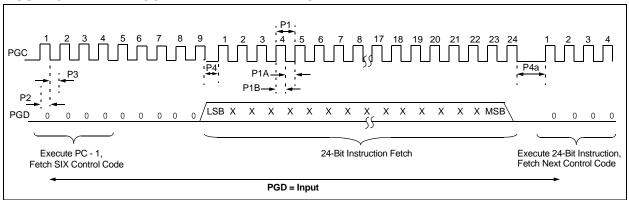

FIGURE 6-3: SIX SERIAL EXECUTION

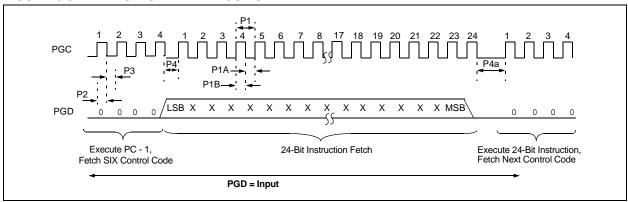

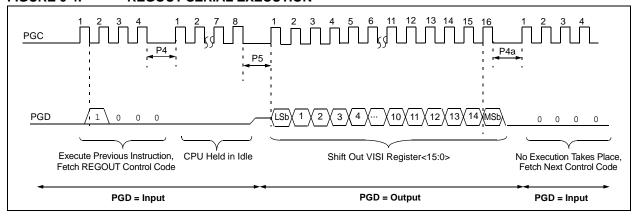

FIGURE 6-4: REGOUT SERIAL EXECUTION

6.4 Flash Memory Programming in ICSP Mode

6.4.1 PROGRAMMING OPERATIONS

Flash memory write and erase operations are controlled by the NVMCON register. Programming is performed by setting NVMCON to select the type of erase operation (Table 6-2) or write operation (Table 6-3) and initiating the programming by setting the WR control bit (NVMCON<15>).

In ICSP mode, all programming operations are self-timed. There is an internal delay between the user setting the WR control bit and the automatic clearing of the WR control bit when the programming operation is complete. Please refer to Section 9.0 "AC/DC Characteristics and Timing Requirements" for detailed information about the delays associated with various programming operations.

TABLE 6-2: NVMCON ERASE OPERATIONS

NVMCON Value	Erase Operation
0x400F	Erase all primary and auxiliary program Flash memory, executive memory and CodeGuard™ Configuration registers (does not erase Unit ID or Device ID registers).
0x400E	Erase all primary and auxiliary user program Flash memory and CodeGuard Configuration registers (does not erase Unit ID or Device ID registers).
0x400D	Erase entire primary program Flash memory and FGS Configuration register.
0x400A	Erase entire auxiliary program Flash memory and FAS Configuration register.
0x4003	Erase a page of code memory or executive memory.

TABLE 6-3: NVMCON WRITE OPERATIONS

NVMCON Value	Write Operation
0x4002	Program 1 row (128 instruction words) of primary or auxiliary Flash memory or executive memory.
0x4001	Program an even-odd pair of words in primary or auxiliary Flash memory.
0x4000	Write a Configuration register byte.

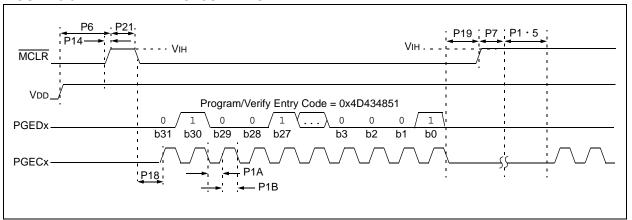

6.4.2 STARTING AND STOPPING A PROGRAMMING CYCLE

The WR bit (NVMCON<15>) is used to start an erase or write cycle. Setting the WR bit initiates the programming cycle.

All erase and write cycles are self-timed. The WR bit should be polled to determine if the erase or write cycle has been completed. Starting a programming cycle is performed as follows:

BSET NVMCON, #WR

FIGURE 6-5: ENTERING ICSP™ MODE

REGISTER 6-1: NVMCON: NON-VOLATILE MEMORY (NVM) CONTROL REGISTER

R/SO-0 ⁽¹⁾	R/W-0 ⁽¹⁾	R/W-0 ⁽¹⁾	R/W-0	U-0	U-0	U-0	U-0

R = Readable bit	W = Writable bit	U = Unimplemented bit, read	d as '0'
-n = Value at POR	'1' = Bit is set	'0' = Bit is cleared	x = Bit is unknown

bit 15 WR: Write Control bit

- 1 = Initiates a Flash memory program or erase operation. The operation is self-timed and the bit is cleared by hardware once operation is complete
- 0 = Program or erase operation is complete and inactive
- bit 14 WREN: Write Enable bit
 - 1 = Enable Flash program/erase operations
 - 0 = Inhibit Flash program/erase operations
- bit 13 WRERR: Write Sequence Error Flag bit
 - 1 = An improper program or erase sequence attempt or termination has occurred (bit is set automatically on any set attempt of the WR bit)
 - 0 = The program or erase operation completed normally
- bit 12 **NVMSIDL:** NVM Stop-in-Idle Control bit⁽²⁾
 - 1 = Discontinue primary and auxiliary Flash operation when the device enters Idle mode
 - 0 = Continue primary and auxiliary Flash operation when the device enters Idle mode
- bit 11-4 Unimplemented: Read as '0'
- bit 3-0 **NVMOP<3:0>:** NVM Operation Select bits^(3,5)
 - 1111 = User memory (primary and auxiliary Flash) and executive memory bulk erase operation
 - 1110 = User memory bulk erase operation (primary and auxiliary Flash)
 - 1101 = Bulk erase primary program Flash memory
 - 1100 = Reserved
 - 1011 = Reserved
 - 1010 = Bulk erase auxiliary program Flash memory
 - 0011 = Memory page erase operation
 - 0010 = Memory row program operation
 - 0001 = Memory double-word (even-odd pair of words aligned at an address that is a multiple of 0x4) program operation
 - 0000 = Program a single configuration register byte
 - Note 1: These bits can only be reset on POR.
 - 2: When exiting Idle mode, there is a delay (TNPD) before Flash memory becomes operational.
 - 3: All other combinations of NVMOP<3:0> are unimplemented.
 - 4: The entire segment is erased with the exception of IVT.
 - 5: Execution of the PWRSAV instruction is ignored while any of the NVM operations are in progress.

6.5 Erasing Program Memory

The procedure for erasing program memory (all of primary Flash memory, auxiliary Flash memory, executive memory and code-protect Configuration bits) consists of setting NVMCON to 0x400F and then executing the programming cycle. For segment erase operations, the NVMCON value should be modified suitably, according to Table 6-2.

Figure 6-6 shows the ICSP programming process for Bulk Erasing program memory. This process includes the ICSP command code, which must be transmitted (for each instruction) Least Significant bit first, using the PGC and PGD pins (see Figure 6-2).

Note: Program memory must be erased before writing any data to program memory.

_	_		ally time 'P11' msec (see Section 9.0 "AC/DC Characteristics and	
		Timing	Requirements") to allow sufficient time for the Bulk Erase operation to	
		comple	ete.	

6.6 Writing Code Memory

The procedure for writing code memory (primary or auxiliary Flash) is similar to the procedure for writing the Configuration registers, except that 128 instruction words are programmed at a time. To facilitate this operation, working registers, W0:W5, are used as temporary holding registers for the data to be programmed.

Table 6-5 shows the ICSP programming details, including the serial pattern with the ICSP command code, which must be transmitted Least Significant bit first using the PGC and PGD pins (see Figure 6-2). In Step 1, the Reset vector is exited.

To minimize the programming time, the same packed instruction format that the programming executive uses is utilized (Figure 5-4). In Step 2, the pointer and TBLPAG register are configured to point to the start of the latch block (0xFA0000). In Step 3, four packed instruction words are stored in working registers, W0:W5, using the MOV instruction and the read pointer, W6, is initialized. The contents of W0:W5 holding the packed instruction word data are shown in Figure 6-7. In Step 4, eight TBLWT instructions are used to copy the data from W0:W5 to the write latches. Since code memory is programmed 128 instruction words at a time, Steps 3-4 are repeated 32 times to load all the write latches (Step 5). The NVMADRU/NVMADR register-pair are then initialized to point to the correct row address.

After the write latches are loaded, programming is initiated by writing to the NVMCON register in Step 7 and setting the WR bit in Step 8. In Step 9, the internal PC is reset to 0x200 every time the NVMCON register is inspected for polling the WR bit. This is a precautionary measure to prevent the PC from incrementing into unimplemented memory when large devices are being programmed. Lastly, in Step 10, Steps 2-9 are repeated until all of code memory is programmed.

Note 1: These three NOP instructions must be transmitted with a clock frequency greater than 2 MHz.

6.7 Writing Configuration Memory

The 8-bit Configuration registers are programmable, one register at a time. The default programming values recommended for the Configuration registers are shown in Table 6-6. The recommended default FOSCSEL value is 0x87, which selects the FRC clock oscillator setting. Just like code memory, Configuration registers are programmed by first setting up the programmed value in a latch (located at address 0xFA0000), specifying the configuration register address in the NVMADRU and NVMADR registers, and then initiating a configuration write operation.

The FGS and FAS Configuration registers are special since they enable code protection for the device. For security purposes, once any bit in these registers is programmed to '0' (to enable code protection), it can only be set back to '1' by performing a Bulk Erase as described in Section 6.5 "Erasing Program Memory".

TABLE 6-6: DEFAULT CONFIGURATION REGISTER VALUES

Address	Name	Default Value

6.8 Reading Code Memory

Reading from code memory (primary or auxiliary Flash) is performed by executing a series of TBLRD instructions and clocking out the data using the REGOUT command.

Table 6-8 shows the ICSP programming details for reading code memory. In Step 1, the Reset vector is exited. In Step 2, the 24-bit starting source address for reading is loaded into the TBLPAG register and W6 register. The upper byte of the starting source address is stored in TBLPAG and the lower 16 bits of the source address are stored in W6.

To minimize the reading time, the packed instruction word format that was utilized for writing is also used for reading (see Figure 6-7). In Step 3, the write pointer, W7, is initialized. In Step 4, two instruction words are read from code memory and clocked out of the device, through the VISI register, using the REGOUT command. Step 4 is repeated until the desired amount of code memory is read.

6.9 Reading Configuration Memory

The procedure for reading configuration memory is similar to the procedure for reading code memory, except that 16-bit data words are read (with the upper byte read being all '0's) instead of 24-bit words. Since there are eight Configuration registers, they are read one register at a time.

Table 6-9 shows the ICSP programming details for reading all of the configuration memory. Note that the TBLPAG register is hard coded to 0xF8 (the upper byte address of configuration memory) and the read pointer, W6, is initialized to 0x0004.

TABLE 6-9: SERIAL INSTRUCTION EXECUTION FOR READING ALL CONFIGURATION MEMORY

0000	000000	NOP							
0000	000000	NOP							
0000	000000	NOP							

6.10 Verify Code Memory and Configuration Word

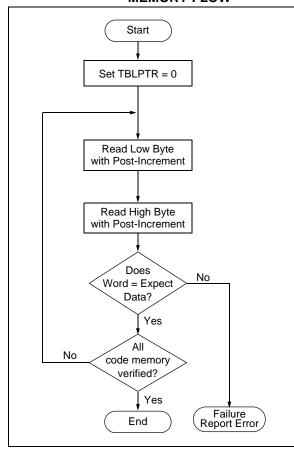

The verify step involves reading back the code memory space and comparing it against the copy held in the programmer's buffer. The Configuration registers are verified with the rest of the code.

The verify process is shown in the flowchart in Figure 6-9. Memory reads occur a single byte at a time, so two bytes must be read to compare against the word in the programmer's buffer. Refer to **Section 6.8** "Reading Code Memory" for implementation details of reading code memory.

Note:

Because the Configuration registers include the device code protection bit, code memory should be verified immediately after writing, if the code protection is enabled. This is because the device will not be readable or verifiable if a device Reset occurs after the code-protect bit in the FGS or FAS Configuration register has been cleared.

FIGURE 6-9: VERIFY CODE MEMORY FLOW

6.11 Reading the Application ID Word

The Application ID Word is stored at address 0x8007F0 in executive code memory. To read this memory location, you must use the SIX control code to move this program memory location to the VISI register. Then, the REGOUT control code must be used to clock the contents of the VISI register out of the device. The corresponding control and instruction codes that must be serially transmitted to the device to perform this operation are shown in Table 6-10.

After the programmer has clocked out the Application ID Word, it must be inspected. If the application ID has the value 0xDD, the programming executive is resident in memory and the device can be programmed using the mechanism described in Section 3.0 "Device Programming – Enhanced ICSP". However, if the application ID has any other value, the programming executive is not resident in memory; it must be loaded to memory before the device can be programmed. The procedure for loading the programming executive to memory is described in Section 7.0 "Programming the Programming Executive to Memory".

6.12 Exiting ICSP Mode

Exiting Program/Verify mode is done by removing VIH from MCLR, as shown in Figure 6-10. The only requirement for exit is that an interval P16 should elapse between the last clock and program signals on PGC and PGD before removing VIH.

FIGURE 6-10: EXITING ICSP™ MODE

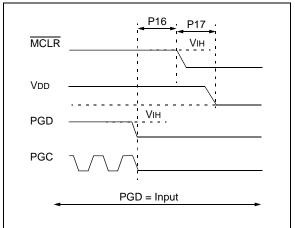

TABLE 6-10: SERIAL INSTRUCTION EXECUTION FOR READING THE APPLICATION ID WORD

Command (Binary)	Data (Hex)	Description

7.0 PROGRAMMING THE PROGRAMMING EXECUTIVE TO MEMORY

7.1 Overview

If it is determined that the programming executive is not present in executive memory (as described in Section 3.2 "Confirming the Presence of the

Programming Executive"), it must be programmed into executive memory using ICSP, as described in **Section 6.0** "**Device Programming – ICSP**".

Storing the programming executive to executive memory is similar to normal programming of code memory. Namely, the executive memory must first be erased, and then the programming executive must be programmed 128 words at a time. This control flow is summarized in Table 7-1.

TABLE 7-1: PROGRAMMING THE PROGRAMMING EXECUTIVE

TABLE 7-1:		ING THE PROGRAMMING EXECUTIVE
Command (Binary)	Data (Hex)	Description
Step 1: Exit th	e Reset vector and	d erase executive memory.
0000	000000	NOP
0000	000000	NOP
0000	000000	NOP

0000	000000	NOP						
0000	000000	NOP						
	<u> </u>	Repeat until the WR bit is clear.						
Step 12: Repe	eat Steps 6-11 until	all 16 rows of executive memory have been programmed.						

Note 1: These three NOP instructions must be transmitted with a clock frequency greater than 2 MHz.

7.2 Programming Verification

After the programming executive has been programmed to executive memory using ICSP, it must be verified. Verification is performed by reading out the contents of executive memory and comparing it with the image of the programming executive stored in the programmer.

Reading the contents of executive memory can be performed using the same technique described in **Section 6.8 "Reading Code Memory"**. A procedure for reading executive memory is shown in Table 7-2. Note that in Step 2, the TBLPAG register is set to 0x80, such that executive memory may be read.

TABLE 7-2: READING EXECUTIVE MEMORY

Command (Binary)	Data (Hex)		Description
Step 1: Exit the	Reset vector.	·

8.0 DEVICE ID

The device ID region of memory can be used to determine mask, variant and manufacturing information about the chip. The device ID region is 2×16 bits and it can be read using the <code>READC</code> command. This region of memory is read-only and can also be read when code protection is enabled.

Table 8-1 lists the identification information for each device.

Table 8-2 shows the Device ID registers.

Register 8-1 provides the JTAG ID register format.

P21	TMCLRH	MCLR High Time	_	500	μs	_

Note 1: VDD must also be supplied to the AVDD and VUSB pins during programming. AVDD and AVSS should always be within ±0.3V of VDD and VSS, respectively.

^{2:} Time depends on the FRC accuracy and the value of the FRC Oscillator tuning register. Refer to the "Electrical Characteristics" chapter in the specific device data sheet.

APPENDIX A: HEX FILE FORMAT

Flash programmers process the standard HEX format used by the Microchip development tools. The format supported is the Intel[®] HEX32 Format (INHX32). Please refer to Appendix A in the "MPASMTM Users Guide" (DS33014) for more information about hex file formats.

The basic format of the hex file is:

:BBAAAATTHHHH...HHHHCC

Each data record begins with a 9-character prefix and always ends with a 2-character checksum. All records begin with ':' regardless of the format. The individual elements are described below.

- BB is a two-digit hexadecimal byte count representing the number of data bytes that appear on the line. Divide this number by two to get the number of words per line.
- AAAA is a four-digit hexadecimal address representing the starting address of the data record. Format is high byte first followed by low byte. The address is doubled because this format only supports 8 bits. Divide the value by two to find the real device address.
- TT is a two-digit record type that will be '00' for data records, '01' for end-of-file records and '04' for extended-address record.
- нннн is a four-digit hexadecimal data word.
 Format is low byte followed by high byte. There will be BB/2 data words following TT.
- CC is a two-digit hexadecimal checksum that is the two's complement of the sum of all the preceding bytes in the line record.

Because the Intel hex file format is byte-oriented, and the 16-bit program counter is not, program memory sections require special treatment. Each 24-bit program word is extended to 32 bits by inserting a so-called "phantom byte". Each program memory address is multiplied by 2 to yield a byte address.

As an example, a section that is located at 0x100 in program memory will be represented in the hex file as 0x200.

The hex file will be produced with the following contents:

- :020000040000fa
- :040200003322110096
- :0000001FF

Notice that the data record (line 2) has a load address of 0200, while the source code specified address 0x100. Note also that the data is represented in "little-endian" format, meaning the Least Significant Byte (LSB) appears first. The phantom byte appears last, just before the checksum.

APPENDIX B: REVISION HISTORY

Revision A (December 2009)

This is the initial released version of this document.

Revision B (June 2011)

This revision includes the following updates:

- Updated Section 2.1 "Required Connections"
- Added the VUSB pin reference to the list of Pin Names and to Note 1 of Pins Used During Programming (Table 2-1)
- Removed Section 2.3 "Pins Used During Programming"
- Add the following devices to Code Memory Size (Table 2-2), Device IDs and Revision (Table 8-1):
 - dsPIC33EP512GP806
 - dsPIC33EP512MC806
 - PIC24EP512GP806
- Updated the Program Memory Map (Figure 2-2)
- Updated the interval time in the next to last paragraph of Section 3.3 "Entering Enhanced ICSP Mode"
- Updated Entering Enhanced ICSP™ Mode (Figure 3-3)
- Renumbered and updated Section 4.0 "Checksum Computation"
- Updated the interval time in the next to last paragraph of Section 6.2 "Entering ICSP Mode"
- Updated Entering ICSP™ Mode (Figure 6-5)
- These changes were made to the AC/DC Characteristics and Timing Requirements (Table 9-1):
 - Updated the Min value for parameter D111
 - Updated the Max value for parameter D113
 - Added parameter D114
 - Removed parameter D013
 - Updated the Max value and the conditions for parameter D80
 - Updated the Min value and the conditions for parameter D90
 - Updated the Min and Max values for parameter P17
 - Updated the Units for parameter P18
 - Added the VUSB pin reference to Note 1
- Updates to formatting and minor text changes were incorporated throughout the document.

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the
 intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

QUALITY MANAGEMENT SYSTEM

CERTIFIED BY DNV

ISO/TS 16949:2009

Microchip received ISO/TS-16949:2002 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEELOQ® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
